6. Services Page: Team Packages and Delivery Process

ENGAGEMENT MODEL

The Services page presents dedicated-team packages for customers seeking engineering resources at different scales. Prices below are displayed website amounts, not formal quotations; current scope and terms should be confirmed.

Package	Displayed Price	Team Composition Summary
Launch	$10,000+/month	Core frontend and backend development, account management, and part-time project management, QA, design, and DevOps support.
Growth	$20,000+/month	Frontend and backend developers, product design, QA, technical project management, and AI-powered development integration.
Scale	$50,000+/month	Larger team including frontend, multiple backend roles, mobile development, QA, DevOps, technical project management, design, and advanced DevOps/AI integration.

Delivery process: The published process begins with an inquiry and discussion of the idea. The customer and company align on requirements, scope, legal terms, timeline, and contract. Work is mapped into specifications and milestones, developed with progress updates or demos, tested, launched, and supported.

- **Initial contact:** Submit an inquiry; the page says the team aims to respond within 24 hours.
- **Discovery:** Discuss the business problem, users, requirements, and project boundaries.
- **Agreement:** Align on scope, legal terms, estimated timeline, and commercial conditions.
- **Project mapping:** Break work into features, milestones, specifications, and a delivery plan.
- **Build and launch:** Develop, share progress, test, assist with setup, and provide support or updates.

7. Portfolio Highlights (Part 1: Enterprise & Sector Systems)

DELIVERED EXAMPLES

The portfolio is intended to demonstrate the types of software the company says it has delivered. These are examples from the website, rather than a complete project register.

- **AI-enabled e-commerce operations platform:** Described as supporting product discovery, order processing, inventory intelligence, recommendations, and operational automation—connecting the company's AI messaging with a practical commerce workflow.
- **Inventory management for sales floors:** The described system includes point of sale (POS), stock monitoring, purchase management, branch/business management, HRM, and accounting or financial modules, illustrating an integrated operations application.
- **Education and learning:** An online learning platform for students demonstrates work in digital learning services and web-based educational experiences.

7. Portfolio Highlights (Continued: Healthcare, Consumer Apps & Web Platforms)

- **Healthcare and home-care:** Examples include a home-care reservation system for patients and a health-management mobile app, representing booking and health-related digital workflows.
- **Mobile apps and games:** An ID-check mobile app and an Android word game demonstrate work across utility applications and interactive consumer experiences.
- **Business platforms and websites:** Other examples include an online job portal, JB Communication and Daily Mart e-commerce sites, Colle Pochi, Scalably community, Sarker Siivoukseen, Elmi Laboratory appointment website, and Royal Bakery corporate website.

Project-specific technology notes: Some project descriptions mention React/Next.js, Node.js or Golang services, REST APIs, event-driven processing, PostgreSQL, Redis, Elasticsearch, Docker, Kubernetes, and queue-based workers. These are project-specific notes.

8. Recent Work

FEATURED INNOVATIONS

This section highlights four recent or featured projects to give visitors a clearer view of the company's current AI, voice-technology, and high-performance developer tooling capabilities. The descriptions are written as project summaries based on the project names and intended functionality supplied for this document; they should be reviewed against the actual implemented features before publication.

8.1 AI Lead Hunting Platform: An AI-powered lead generation platform designed to help businesses discover and qualify potential customers more efficiently. A user defines a campaign by providing a company website, target customer profile (ideal customer profile or ICP), desired lead criteria, and target geography. The system can generate search queries, collect candidate companies from business discovery sources, verify official websites, gather supporting evidence, and score candidates against the campaign's requirements. The goal is to deliver a smaller, more relevant list of qualified leads rather than an unverified directory of names. Potential workflow features include campaign management, ICP review, candidate discovery, website verification, lead enrichment, qualification scoring, and export of qualified lead data.

8.2 RAG Voice Agent: A voice-based AI assistant that can answer questions using information retrieved from a defined knowledge base. Retrieval-Augmented Generation (RAG) allows the agent to look up relevant documents or records before generating an answer, helping it respond with information grounded in the available source material rather than relying only on general model knowledge. A voice interface can let users ask questions naturally and hear spoken responses, making the knowledge assistant useful for hands-free or conversational access to business information. The exact knowledge sources, citation behavior, integrations, and supported languages should be documented according to the implemented version.

8. Recent Work (Continued: Real-Time Voice Translation & High-Speed Coding LLM Infrastructure)

8.3 Voice Translator: A real-time or near-real-time voice translation solution intended to help people who speak different languages communicate more easily in online meetings or conversations. The intended workflow can capture a speaker's audio, transcribe or process the speech, translate the content into a listener's preferred language, and deliver translated audio to that listener. A manual language-selection feature can allow each participant to choose the language they want to hear, without requiring automatic detection of every participant's preferred listening language. Depending on the implementation, the system may use a real-time audio platform, speech processing, translation models, and text-to-speech generation. Supported meeting platforms, languages, latency, and speaker-attribution behavior should be confirmed against the current build.

8.4 Self-Hosted Claude-Class Coding LLM & High-Speed Developer CLI

IN-HOUSE AI INFRASTRUCTURE

A custom-engineered, Claude-class coding and deep-reasoning AI platform deployed on dedicated self-hosted server infrastructure. Built specifically for elite software engineers, the project pairs an advanced quantized coding model with a custom Command-Line Interface (CLI) to deliver ultra-high-speed generation and maximum multi-step reasoning at a fraction of commercial API costs:

- **Server Deployment & Precision Quantization:** Hosted on dedicated in-house servers with advanced model quantization, optimizing GPU memory footprint while preserving deep code-synthesis accuracy and complex architectural reasoning comparable to Claude.
- **KTransformers, Coder & Triton Acceleration:** Combines specialized Coder weights, **KTransformers** heterogeneous optimization, and **Triton** inference kernels to ensure maximum reasoning depth at ultra-high token generation speeds.
- **Purpose-Built CLI for Best Coders:** Provides a terminal-native developer CLI supporting repository-wide context analysis, multi-file code generation, automated refactoring, debugging, and agentic developer workflows.
- **Unlimited 30-Day Server Access & High Cost Efficiency:** Operates on an unrestricted **30-day unlimited usage cycle** on self-managed servers without per-token throttling, achieving substantially lower operational costs than commercial Claude subscriptions or API tiers.

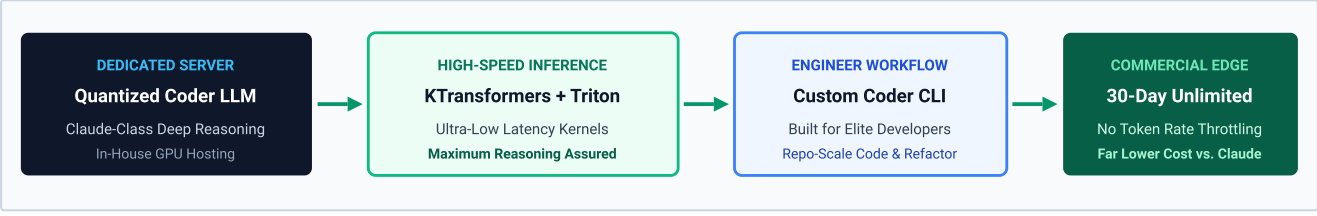

Figure 8.1: Technical stack and operational advantage of Project 8.4 (Self-Hosted Coding LLM & Developer CLI).
